85796 rows × 8 columns

Step 1 Split the dataset into training and test sets (80, 20).

```
In [20]: from sklearn.model_selection import train_test_split
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2)
```

Step 2(a) Use all the features to fit the linear regression model for feature (ReFoundByShelter) using the training set.

```
In [21]: from sklearn.linear_model import LinearRegression
    regr=LinearRegression()
    regr.fit(X_train,y_train)
    y_pred=regr.predict(X_test)
```

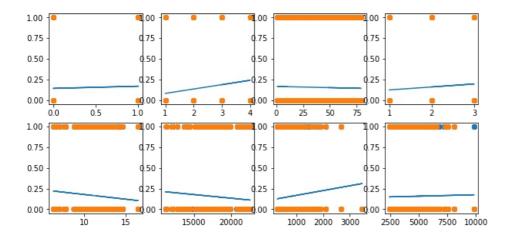

Step 2(b) Report the coefficients, mean squared error and variance score for the model on the test set.

Step 3(a) Use each feature alone - to fit a linear regression model on the training set.

Step 3(b) Report the coefficient, mean squared error and variance score for the model on the test set. Also report the plots of the linear regression models generated on each feature. Each plot should distinctly show the training points, test points and the linear regression line.

```
In [23]: plt.figure(figsize=(10,10))
          names=["Gender", "Age", "Intelligence-Ranking", "Size-Category", "Longevity", "Total-Cost($)", "Purchase-Cost($)")
          for i in range(8):
              plt.subplot(4, 4, i + 1)
              x=pd.DataFrame(X.iloc[:,i])
              x_train, x_test, y_train, y_test = train_test_split(x, y, test_size=0.2)
              regr = LinearRegression()
              regr.fit(x_train, y_train)
              y pre =regr.predict(x test)
              plt.scatter(x_train, y_train, label='train')
              plt.scatter(x_test, y_test, label='test')
              plt.plot(x_test.values.reshape(-1,1) , y_pre,label='line')
              print('for fit on feature: '+names[i])
              # The coefficients
              print('Coefficients: ', regr.coef_)
              # The mean squared error
              print("Mean squared error: %.2f" % (np.sum((y_pre-y_test)**2)/len(y_test)))
              # Explained variance score : 1 is perfect prediction
print('Variance score: %.2f' % regr.score(x test,y test))
              print('\n')
          plt.show()
```

Step 4(a) Perform 10 iterations of (Step 1, Step 2(a), and Step 3(a)).

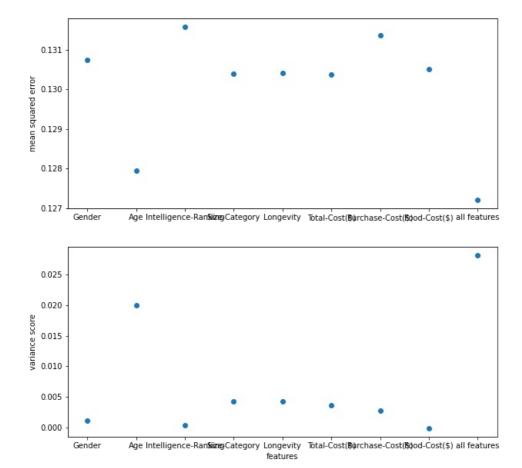

Step 4(b) • During each iteration of Step4(a), gather the metrics - mean squared error and variance score for the models on the test set • For each feature, compute the average, over the 10 iterations, of each evaluation metric. Do the same for the metrics corresponding to 'all features'.

Conclusion & Discussion

From the linear regression model, we can see:

- 1. Age and Purchase-Cost have tiny effects on if a pet is re-found. Aging and more purchase-cost pets seem to have a trend to be re-found more than one time.
- 2. Age is the most predictive for the target feature. It has a low average of mean squared error and high average of variance score.
- 3. The model performs much better with all features rather than any individual ones. This quite makes sense since the model is better trained. Some features fit the model quite well though some others do not have a quite relatively linear relationship.
